601.220 Intermediate Programming

Spring 2023, Day 30 (April 7th)

Today's agenda

- Review exercise 29
- Day 30 recap questions
- Exercise 30

Reminders/Announcements

- HW6 is due this evening by 11 pm
 - Written assignment, no late submissions
- HW7 is due Friday, April 14th by 11 pm
- Final project team formation (2–3 members per team)
 - Submit the Google form in Piazza post 571 (pinned) by 11 am on Tuesday, April 11th
 - If you aren't registered on a team by the deadline, you will be assigned to a team

Overloading the output stream insertion operator for the Complex class:

```
// in complex.h (in the Complex class definition)
  friend std::ostream& operator << (std::ostream &out,
                                   const Complex &c);
// in complex.cpp
  std::ostream& operator<<(std::ostream &out,</pre>
                            const Complex &c) {
    out << c.rel << " + " << c.img << "i";
    return out;
```

Copy constructor and assignment operator

```
// in complex.cpp
  Complex::Complex(const Complex &other)
    : rel(other.rel), img(other.img) {
  }
  Complex& Complex::operator=(const Complex &rhs) {
    if (this != &rhs) {
      rel = rhs.rel;
      img = rhs.img;
    return *this;
  }
```

Overloaded operators for arithmetic, in complex.h (in the class definition for the Complex class):

```
Complex operator+(const Complex& rhs) const;
Complex operator-(const Complex& rhs) const;
Complex operator*(const Complex& rhs) const;
Complex operator*(const float& rhs) const;
Complex operator/(const Complex& rhs) const;
```

Since these are defined as member functions, they only need one parameter, which is the right-hand-side operand. (The left hand Complex object in the expression will be the receiver object.)

Implementations of arithmetic operators in complex.cpp:

```
Complex Complex::operator+(const Complex& rhs) const {
   Complex sum(rel+rhs.rel, img+rhs.img);
   return sum;
}
Complex Complex::operator-(const Complex& rhs) const {
   return *this + (rhs * -1.0f);
}
```

Implementation of multiplication:

Non-member * operator for float times Complex:

```
// in complex.h
friend Complex operator*(float lhs, const Complex &rhs);
// in complex.cpp
Complex operator*(float lhs, const Complex &rhs) {
   return rhs * lhs;
}
```

This operator can't be a member function because the value on the left-hand-side is not an object. Also, this function technically doesn't need to be a friend because it invokes the public Complex times float operator.

Day 30 recap questions

- What is difference between initialization and assignment?
- 2 Does the line f2 = f1; use initialization or assignment (assume Foo is a class and f1 and f2 are both of type Foo)?
- Ooes the line Foo f2 = f1; use initialization or assignment (assume Foo is a class and f1 is of type Foo)?
- What is a shallow copy and what is a deep copy?
- **6** What is the rule of 3?

1. What is difference between initialization and assignment?

Initialization: a constructor is called when an object's lifetime begins.

Assignment: the = operator (assignment) is used to assign new data to an existing object, replacing its current contents.

Examples:

```
std::string s("hello");  // initialization of s
std::string s2 = "hello again"; // initialization of s2
std::string s3;  // initialization of s3
// using default ctor
s3 = s;  // assignment to s3
```

2. Does the line f2 = f1; use initialization or assignment (assume Foo is a class and f1 and f2 are both of type Foo)?

Assignment. It is not a variable declaration of f2, so f2 has already been initialized.

3. Does the line Foo f2 = f1; use initialization or assignment (assume Foo is a class and f1 is of type Foo)?

Initialization. This is a variable declaration of f2, and f1 is being provided as the initial value, so the copy constructor is called to initialize f2 with f1's contents.

4. What is a shallow copy and what is a deep copy?

Deep copy: replicate dynamically-allocated objects/arrays.

Shallow copy: just copy pointers to dynamically-allocated objects/arrays.

```
Example class:
```

```
cass CBuf {
private:
    char *buf; int capacity;
pubic:
    CBuf(int capacity)
    : buf(new char[capacity]), capacity(capacity) { }
    CBuf(const CBuf &other); // copy ctor
    // ...other member functions...
};
```

Copy constructor using deep copy

```
CBuf::CBuf(const CBuf &other)
: buf(new char[other.capacity])
, capacity(other.capacity) {
  for (int i = 0; i < capacity; i++) {
    buf[i] = other.buf[i];
  }
}</pre>
```

The new object will have its own dynamically-allocated array, distinct from the original object.

Copy constructor using shallow copy

```
CBuf::CBuf(const CBuf &other)
   : buf(other.buf), capacity(other.capacity) {
}
```

Shallow copy means two objects have pointers to the same dynamically-allocated array. If one object modifies the array, the changes are visible in the other object (because they are "sharing" the array.) Also: which object's constructor should delete it?

Shallow copy vs. deep copy

Shallow copy tends to be problematic because either

- Multiple objects try to deallocate the dynamic memory (double free, a serious memory error)
- No object tries to deallocate the dynamic memory (memory leak, also a fairly serious bug)

If you are implementing a class that manages dynamic memory, the copy constructor and assignment operator should do deep copy.

5. What is the rule of 3?

If a class has a non-trivial destructor (e.g., the destructor deletes a dynamically-allocated object or array), then it also needs

- a copy constructor
- an assignment operator

Both of these should do a deep copy.

Disabling value semantics

Alternately: a class with a nontrivial destructor could *prohibit* the copy constructor and assignment operator from being used by defining them in the class definition as private, and then not defining them.

The disadvantage of this approach is that the class will not have *value semantics*. So you can't copy, assign, pass by value, return by value, etc.

A subtle issue with assignment

Consider the following assignment operator:

```
CBuf &CBuf::operator=(const CBuf &rhs) {
  delete[] buf;
  buf = new char[rhs.capacity];
  capacity = rhs.capacity;
  for (int i = 0; i < capacity; i++) {
    buf[i] = rhs.buf[i];
  }
  return *this;
}</pre>
```

Can you spot the problem? (It is very subtle.)

Guarding against self-assignment

We can't rule out the possibility that an object might be assigned to itself!

While this (probably) wouldn't happen explicitly, it could happen fairly easily because of references:

Buggy version of assignment operator

```
CBuf &CBuf::operator=(const CBuf &rhs) {
  delete[] buf;
  buf = new char[rhs.capacity];
  capacity = rhs.capacity;
  for (int i = 0; i < capacity; i++) {
    buf[i] = rhs.buf[i];
  }
  return *this;
}</pre>
```

Think about what happens when rhs and *this are the same object. The character array is deleted, but then we try to copy data from the uninitialized newly-allocated character array.

Fixing the bug

```
CBuf &CBuf::operator=(const CBuf &rhs) {
  if (this != &rhs) {
    delete[] buf;
    buf = new char[rhs.capacity];
    capacity = rhs.capacity;
    for (int i = 0; i < capacity; i++) {
        buf[i] = rhs.buf[i];
    }
  }
  return *this;
}</pre>
```

Now the assignment properly does nothing if rhs and *this are the same object.

You should get into the habit of using this idiom when you implement assignment operators.

Exercise 30

- Linked list impementation in C++
- Implementation of copy constructor and assignment operator using deep copy
- Talk to us if you have questions!
